1. Un solido (τ, L, θ) tiene la ecuación de estado

$$\tau = k\theta^2 \left(\frac{L}{L_0} - \frac{L_0^2}{L^2} \right); k, L_0 = \text{ctes}$$

Calcular:

$$Y = \frac{L}{A} \left(\frac{d\tau}{dL} \right)_\theta$$

$$\alpha = \frac{1}{L} \left(\frac{dL}{d\theta} \right)_\tau$$

Solución.

Para $\tau(L, \theta)$, tenemos

$$d\tau = \left(\frac{d\tau}{dL} \right)_\theta dL + \left(\frac{d\tau}{d\theta} \right)_L d\theta$$

Por otra parte,

$$\begin{aligned} d\tau &= d \left(k\theta^2 \left(\frac{L}{L_0} - \frac{L_0^2}{L^2} \right) \right) \\ &= kd \left(\theta^2 \left(\frac{L}{L_0} - \frac{L_0^2}{L^2} \right) \right) \\ &= k \left[\theta^2 dL + 2\theta \left(\frac{L}{L_0} - \frac{L_0^2}{L^2} \right) d\theta \right] \\ &= k\theta^2 dL + 2k\theta \left(\frac{L}{L_0} - \frac{L_0^2}{L^2} \right) d\theta \end{aligned}$$

Y, por las igualdades anteriores

$$\begin{aligned} \left(\frac{d\tau}{dL} \right)_\theta dL + \left(\frac{d\tau}{d\theta} \right)_L d\theta &= k\theta^2 dL + 2k\theta \left(\frac{L}{L_0} - \frac{L_0^2}{L^2} \right) d\theta \\ \left(\frac{d\tau}{dL} \right)_\theta &= k\theta^2 \quad y \quad \left(\frac{d\tau}{d\theta} \right)_L = 2k\theta \left(\frac{L}{L_0} - \frac{L_0^2}{L^2} \right) \end{aligned}$$

Busquemos $\left(\frac{dL}{d\theta} \right)_\tau$, para ello necesitaremos la cíclica

$$\left(\frac{dL}{d\theta} \right)_\tau \left(\frac{d\tau}{dL} \right)_\theta \left(\frac{d\theta}{d\tau} \right)_L = -1$$

$$\begin{aligned}
\left(\frac{dL}{d\theta}\right)_{\tau} &= -\frac{1}{\left(\frac{d\tau}{dL}\right)_{\theta} \left(\frac{d\theta}{d\tau}\right)_L} \\
&= -\frac{\left(\frac{d\tau}{d\theta}\right)_L}{\left(\frac{d\tau}{dL}\right)_{\theta}} \\
&= -\frac{2k\theta \left(\frac{L}{L_0} - \frac{L_0^2}{L^2}\right)}{k\theta^2} \\
&= -\frac{2\left(\frac{L}{L_0} - \frac{L_0^2}{L^2}\right)}{\theta^2}
\end{aligned}$$

Para finalizar,

$$\begin{aligned}
Y &= \frac{L}{A} \left(\frac{d\tau}{dL}\right)_{\theta} = \frac{L}{A} k\theta^2 \\
\alpha &= \frac{1}{L} \left(\frac{dL}{d\theta}\right)_{\tau} = \frac{1}{L} \left(-\frac{2\left(\frac{L}{L_0} - \frac{L_0^2}{L^2}\right)}{\theta^2}\right) = -\frac{2\left(\frac{L}{L_0} - \frac{L_0^2}{L^2}\right)}{L\theta^2}
\end{aligned}$$

2. La ecuación de estado de un Gas (p, v, θ) es

$$p(v - b) = VR\theta e^{-\frac{a}{Rv\theta}}$$

Con $V, R, a, b = cte$

Encuentra

$$\beta = \frac{1}{v} \left(\frac{dv}{d\theta} \right)_p$$

Busquemos $\left(\frac{dv}{d\theta} \right)_p$, para lo que hay que buscar el valor de

$$\begin{aligned} p(v - b) &= VR\theta e^{-\frac{a}{Rv\theta}} \\ \ln(p(v - b)) &= \ln(VR\theta e^{-\frac{a}{Rv\theta}}) \\ \ln p + \ln(v - b) &= \ln V + \ln R + \ln \theta + \ln e^{-\frac{a}{Rv\theta}} \\ \ln p + \ln(v - b) &= \ln V + \ln R + \ln \theta + \left(-\frac{a}{Rv\theta} \right) \\ \ln p + \ln(v - b) &= \ln V + \ln R + \ln \theta - \frac{a}{Rv\theta} \end{aligned}$$

Usemos derivada implícita y recordar que: $P, V, R, a, b = cte$

$$\begin{aligned} 0 + \left(\frac{dv}{d\theta} \right) \frac{1}{v - b} &= 0 + 0 + \frac{1}{\theta} - \left(\frac{a}{R} \right) \left(\frac{(0)(v\theta) - (1) \left(\left(\frac{dv}{d\theta} \right) \theta + v \right)}{(v\theta)^2} \right) \\ \left(\frac{dv}{d\theta} \right) \frac{1}{v - b} &= \frac{1}{\theta} + \left(\frac{a}{R} \right) \left(\frac{\theta + v}{(v\theta)^2} \right) \\ &= \frac{1}{\theta} + \frac{\theta a}{v^2 \theta^2 R} + \frac{\theta v}{v^2 \theta^2 R} \end{aligned}$$

Entonces

$$\begin{aligned} \left(\frac{dv}{d\theta} \right) &= \frac{V - b}{\theta} + \frac{\theta a(v - b)}{v^2 \theta^2 R} + \frac{\theta v(v - b)}{v^2 \theta^2 R} \\ &= \frac{(v\theta R)(v - b)v}{\theta(v^2 \theta R - a(v - b))} \end{aligned}$$

Por lo tanto,

$$\beta = \frac{1}{v} \left(\frac{dv}{d\theta} \right) = \left(\frac{1}{v} \right) \frac{(v\theta R)(v - b)v}{\theta(v^2 \theta R - a(v - b))} = \frac{(v\theta R)(v - b)}{\theta(v^2 \theta R - a(v - b))}$$

3. En un sistema eléctrico (ε, P, θ)

$$\left(\frac{d\varepsilon}{dP}\right)_\theta = \frac{\theta}{a\theta + b}$$

$$\left(\frac{dP}{d\theta}\right)_\varepsilon = -\frac{b}{\theta^2}\varepsilon$$

Encuentra la ecuación de estado.

Como las variables independientes son $\varepsilon, \theta \Rightarrow p(\varepsilon, \theta)$

Entonces

$$\begin{aligned} dp &= \left(\frac{dP}{d\varepsilon}\right)_\theta d\varepsilon + \left(\frac{dP}{d\theta}\right)_\varepsilon d\theta \\ &= \left(\frac{a\theta + b}{\theta}\right) d\varepsilon + \left(-\frac{b}{\theta^2}\varepsilon\right) d\theta \\ &= \left(a + \frac{b}{\theta}\right) d\varepsilon - \frac{b\varepsilon}{\theta^2} d\theta \end{aligned}$$

Por otro lado,

$$dp = f(\theta)g'(\varepsilon) + g(\varepsilon)f'(\theta) = d(f(\theta)g(\varepsilon))$$

Tomamos $f(\theta) = a + \frac{b}{\theta}$ y $g(\varepsilon) = \varepsilon$

Entonces

$$\begin{aligned} dp &= d\left(\left(a + \frac{b}{\theta}\right)(\varepsilon)\right) \\ &= d\left(a\varepsilon + \frac{b}{\theta}\varepsilon\right) \end{aligned}$$

Implica que,

$$\begin{aligned} \int dp &= \int d\left(a\varepsilon + \frac{b}{\theta}\varepsilon\right) \\ p &= a\varepsilon + \frac{b}{\theta}\varepsilon + C \end{aligned}$$

Por lo tanto, la ecuación de estado está dada por:

$$p = a\varepsilon + \frac{b\varepsilon}{\theta} + C$$

4. Para un sólido (τ, L, θ)

$$Y = \frac{L}{A} \left(\frac{d\tau}{dL} \right)_{\theta} = \frac{L}{A} a \theta^2$$
$$\alpha = \frac{1}{L} \left(\frac{dL}{d\theta} \right)_{\tau} = b f(\theta); a, b = cte$$

Encuentra $f(\theta)$ y la ecuación de estado.

Encontremos $f(\theta)$

$$\left(\frac{d\tau}{dL} \right)_{\theta} = a \theta^2$$
$$\left(\frac{dL}{d\tau} \right)_{\theta} = \frac{1}{a \theta^2}$$

Tenemos

$$\left(\frac{d}{d\tau} \left(\frac{dL}{d\theta} \right)_{\tau} \right)_{\theta} = \left(\frac{d}{d\theta} \left(\frac{dL}{d\tau} \right)_{\theta} \right)_{\tau}$$
$$\left(\frac{d}{d\tau} \right)_{\theta} (L b f(\theta)) = \left(\frac{d}{d\theta} \right)_{\tau} \left(\frac{1}{a \theta^2} \right)$$
$$b f(\theta) \left(\frac{d}{d\tau} \right)_{\theta} (L) = - \frac{2}{a \theta^3}$$

Entonces

$$f(\theta) = - \frac{2}{a b \theta^3 \left(\frac{dL}{d\tau} \right)_{\theta}}$$
$$= - \frac{2 \left(\frac{d\tau}{dL} \right)_{\theta}}{a b \theta^3}$$
$$= - \frac{2 a \theta^2}{a b \theta^3}$$
$$= - \frac{2}{\theta b}$$
$$f(\theta) = - \frac{2}{\theta b}$$

Encontremos la ecuación de estado

Como las variables independientes son $L, \theta \Rightarrow \tau(L, \theta)$

Entonces

$$\begin{aligned}d\tau &= \left(\frac{d\tau}{dL}\right)_\theta dL + \left(\frac{d\tau}{d\theta}\right)_L d\theta \\&= (a\theta^2)dL + \left(\frac{d\tau}{d\theta}\right)_L d\theta\end{aligned}$$

Halleemos $\left(\frac{d\tau}{d\theta}\right)_L$ con la cíclica

$$\begin{aligned}\left(\frac{d\tau}{d\theta}\right)_L \left(\frac{d\theta}{dL}\right)_\tau \left(\frac{dL}{d\tau}\right)_\theta &= -1 \\ \left(\frac{d\tau}{d\theta}\right)_L &= -\frac{1}{\left(\frac{d\theta}{dL}\right)_\tau \left(\frac{dL}{d\tau}\right)_\theta} \\ &= -\left(\frac{dL}{d\theta}\right)_\tau \left(\frac{d\tau}{dL}\right)_\theta \\ &= -\left(-\frac{2L}{\theta}\right)(a\theta^2) \\ &= 2aL\theta\end{aligned}$$

Regresamos para sustituir

$$d\tau = (a\theta^2)dL + (2aL\theta)d\theta$$

Por otro lado,

$$d\tau = f(\theta)g'(L) + g(L)f'(\theta) = d(f(\theta)g(L))$$

Tomamos $f(\theta) = \theta^2$ y $g(\varepsilon) = aL$

Entonces

$$\begin{aligned}d\tau &= d(\theta^2(aL)) \\ &= d(aL\theta^2)\end{aligned}$$

Implica que,

$$\begin{aligned}\int d\tau &= \int d(aL\theta^2) \\ \tau &= aL\theta^2 + C\end{aligned}$$

Por lo tanto, la ecuación de estado está dada por:

$$\tau = aL\theta^2 + C$$
